**Kernel Embedding for Particle Gibbs-Based Optimal Control**

Problem description:

Bayesian learning-based control approaches are promising for safety-critical systems where physical modeling is time-consuming or impossible. A common problem in such systems is that not all states can be measured, resulting in the absence of a closed-form expression for the posterior distribution. However, particle Markov chain Monte Carlo (PMCMC) methods like particle Gibbs sampling can draw samples from the posterior distribution. These samples can be used to formulate a scenario optimal control problem (OCP), for whose solution probabilistic constraint satisfaction guarantees can be inferred [1]. However, representing the unknown dynamics using samples is exceedingly inefficient because many samples are required for a good representation. In addition, the scenario OCP must be solved repeatedly to infer probabilistic guarantees.

Kernel embedding is a promising alternative that allows the representation of unknown distributions with few samples, even if their parametric form is unknown. In recent years, this idea has been increasingly used for stochastic optimal control, among others, in [2] and [3]. A major advantage of these approaches is that the desired robustness level can be specified a priori and does not have to be determined by repeatedly solving the OCP.

This thesis thus aims to implement an optimal control approach that combines PMCMC methods for system identification with kernel embedding. Furthermore, the robustness of the proposed approach shall be analyzed, and the resulting algorithm shall be evaluated using simulations.

Tasks:

- Literature research on kernel embedding and PMCMC-based control
- Implementation of an optimal control approach that utilizes kernel embedding
- Robustness analysis of the proposed approach
- Numerical evaluation of the proposed approach

## **Abstract**

A short (1–3 paragraphs) summary of the work. Should state the problem, major assumptions, basic idea of solution, results. Avoid non–standard terms and acronyms. The abstract must be able to be read completely on its own, detached from any other work (e.g., in collections of paper abstracts). Do not use references in an abstract.

# Chapter 1

## Introduction

Your first chapter in the document. Introduce the problem (gently!). Try to give the reader an appreciation of the difficulty, and an idea of how you will go about it. It is like the overture of an opera: it plays on all the relevant themes.

Make sure you clearly state the vision/aims of your work, which problem you are trying to solve, and why it is important. While the introduction is the part that is read first (ignoring title and abstract), it is usually best written last (when you actually know what you have really achieved). Remember, it is the first thing that is read and will have a major influence on the how the reader approaches your work. If you bore them now, you have most likely lost them already. If you make outrageous claims, pretend to solve the world's problems, etc, you are likely fighting an uphill battle later on. Also, make sure you pick up any threads spun in the introduction later on, to ensure that the reader thinks they get what they have been promised. Do not create an expectation that you will deliver more than you actually do. Remember, the reader may be your marker (of a thesis) or referee (of a paper), and you do not want to annoy them.

### 1.1 Problem Statement

Consider the general nonlinear discrete-time system of the form

$$\mathbf{x}_{t+1} = \mathbf{f}(\mathbf{x}_t, \mathbf{u}_t) + \mathbf{v}_t \quad (1.1a)$$

$$\mathbf{y}_t = \mathbf{g}(\mathbf{x}_t, \mathbf{u}_t) + \mathbf{w}_t \quad (1.1b)$$

with the state  $\mathbf{x} \in \mathbb{R}^{n_x \in \mathbb{N}}$ , the input  $\mathbf{u} \in \mathbb{R}^{n_u \in \mathbb{N}}$ , the output  $\mathbf{y} \in \mathbb{R}^{n_y \in \mathbb{N}}$ , the process noise  $\mathbf{v}_t \in \mathbb{R}^{n_x}$ , the measurement noise  $\mathbf{w}_t \in \mathbb{R}^{n_y}$  and time  $t \in \mathbb{Z}$ .

In our setting, only the output  $\mathbf{y}$  is observable and the state transition function  $\mathbf{f}(\cdot)$  and the observation function  $\mathbf{g}(\cdot)$ , as well as the distributions  $\mathcal{V}$  and  $\mathcal{W}$  of the process noise  $\mathbf{v}$  and measurement noise  $\mathbf{w}$  are unknown.

We assume that a dataset  $\mathbb{D} = \{\mathbf{u}_t, \mathbf{y}_t\}_{t=-T:-1}$  containing the last  $T \in \mathbb{N}$  measurements of the input  $\mathbf{u}$  and output  $\mathbf{y}$  is available.

We further assume that the structure of the model  $\{\mathbf{f}_\theta(\cdot), \mathbf{g}_\theta(\cdot), \mathbf{V}_\theta, \mathbf{W}_\theta\}$  is known and is dependent on a finite number of unknown parameters  $\theta$ . In addition to that, the priors  $p(\theta)$  and  $p(\mathbf{x}_{-T})$  are available as well.

The objective is to minimize a given cost function

$$J_H = \sum_{t=0}^H c(\mathbf{u}_t, \mathbf{x}_t, \mathbf{y}_t) \quad (1.2)$$

over the horizon  $H$  while satisfying the constraints

$$\mathbf{h}(\mathbf{u}_{0:H}, \mathbf{x}_{0:H}, \mathbf{y}_{0:H}) \leq \mathbf{0} \quad (1.3)$$

with  $\mathbf{h} \in \mathbb{R}^{n_c}$  being a vector of arbitrary deterministic function. As the states  $\mathbf{x}_{0:H}$  are unknown to us and there are several uncertain factors in our system, the constraints are transformed into chance-constraints and since it is possible that  $\mathbf{h}$  is impossible to satisfy for every possible  $\mathbf{x}_{0:H}$ , we also introduce a risk factor  $\alpha \in [0, 1]$  that relaxes these constraints, turning them into

$$P[h_i(\mathbf{u}_{0:H}, \mathbf{x}_{0:H}, \mathbf{y}_{0:H}) \leq 0] \geq 1 - \alpha, \forall i = 1, \dots, n_c \quad (1.4)$$

with  $h_i$  being the  $i$ -th element of  $\mathbf{h}$  and  $P$  being generally unknown.

## 1.2 Related Work

“The related work section (sometimes called literature review) is just that, a review of work related to the problem you are attempting to solve. It should identify and evaluate past approaches to the problem. It should also identify similar solutions to yours that have been applied to other problems not necessarily directly related to the one your solving. Reviewing the successes or limitations of your proposed solution in other contexts provides important understanding that should result in avoiding past mistakes, taking advantage of previous successes, and most importantly, potentially improving your solution or the technique in general when applied in your context and others.

In addition to the obvious purpose indicated, the related work section also can serve to:

- justify that the problem exists by example and argument
- motivate interest in your work by demonstrating relevance and importance
- identify the important issues
- provide background to your solution

Any remaining doubts over the existence, justification, motivation, or relevance of your thesis topic or problem at the end of the introduction should be gone by the end of related work section.

Note that a literature review is just that, a review. It is not a list of papers and a description of their contents! A literature review should critique, categorize, evaluate, and summarize work related to your thesis. Related work is also not a brain dump of everything you know in the field. You are not writing a textbook; only include information directly related to your topic, problem, or solution.”

Note: Write literature review at an early stage of your project to build on the knowledge of others, not reinvent the wheel over and over again! There is nothing more frustrating after weeks or months of hard work to find that your great solution has been published 5 years ago and is considered old news or that there is a method known that produces superior results.

## Chapter 2

# Technical Approach

In this chapter, an approach is outlined that allows us to effectively solve the chance-constraint problem defined in 1.1. In section 2.1 we draw samples from unknown system and use them to generate scenarios. These scenarios are then used in 2.2 to reformulate and solve the OCP.

### 2.1 Particle Markov Chain Monte Carlo Methods

For practical applications, the known priors  $p(\boldsymbol{\theta})$  and  $p(\mathbf{x}_{-T})$  and the observations  $\mathbb{D}$  must be used to infer the posterior  $p(\boldsymbol{\theta}, \mathbf{x}_{T:-1} \mid \mathbb{D})$ . This is necessary since the repeated propagation of  $p(\mathbf{x}_{-T})$  would otherwise cause an excessively large variance in  $p(\mathbf{x}_{-1})$  making stochastic OCP infeasible. We then draw samples from this distribution are particle Markov chain Monte Carlo (PMCMC) methods which is explained in [ADH10] and will be summarized in this section.

While in general, the inference of the psoterior PMCMC methods  $p(\boldsymbol{\theta}, \mathbf{x}_{T:-1} \mid \mathbb{D})$  is analytically intractable, PMCMC bypass this issue by iteratively drawing samples from  $p(\boldsymbol{\theta} \mid \mathbf{x}_{T:-1}, \mathbb{D})$  and  $p(\mathbf{x}_{T:-1} \mid \boldsymbol{\theta}, \mathbb{D})$  while updating the distributions with the previously drawn set, i.e.  $\mathbf{x}_{T:-1}^{[n]}$  is drawn from  $p(\mathbf{x}_{T:-1}^{[n]} \mid \boldsymbol{\theta}^{[n]}, \mathbb{D})$  and  $\boldsymbol{\theta}^{[n+1]}$  is then drawn from  $p(\boldsymbol{\theta}^{[n+1]} \mid \mathbf{x}_{T:-1}^{[n]}, \mathbb{D})$ . This is repeated until the desired number of samples has been achieved.

To ensure that the samples drawn through this method are an accurate representation of the distribution  $p(\boldsymbol{\theta}, \mathbf{x}_{T:-1})$ , additional steps are taken. For one, the first  $N_p$  samples must be discarded as they are heavily reliant on the initialization and as such might show a strong bias. This burn in period should be chosen large enough so that this bias is no longer reflected in the samples. The samples should also be indepedent of each other which is not given with this method as each  $\boldsymbol{\theta}^{[n]}$  is dependent on  $\mathbf{x}_{T:-1}^{[n]}$  which in turn is dependent on  $\boldsymbol{\theta}^{[n-1]}$ . As such, measures must be taken to reduce the correlation between samples as much as possible. One approach to do this is thinning where only every  $n_d$ -th sample is used and the other samples are discarded. By increasing this parameter, the samples become more uncorrelated

but there will also be a larger amount of samples created which leads to inefficiency.

---

**Algorithm 1** Scenario generation
 

---

**Input:** Dataset  $\mathbb{D}$ , parametric model  $\{\mathbf{f}_\theta(\cdot), \mathbf{g}_\theta(\cdot), \mathcal{V}_\theta, \mathcal{W}_\theta\}$ ,  
priors  $p(\boldsymbol{\theta})$  and  $p(\mathbf{x}_{-T})$ ,  $N, H, T$

**Output:** Scenarios  $\boldsymbol{\delta}^{[1:N]} = \{\boldsymbol{\theta}, \mathbf{x}_0, \mathbf{v}_{0:H}, \mathbf{w}_{0:H}\}^{[1:N]}$

```

1: for  $n = 1, \dots, N$  do
2:   Sample  $\{\boldsymbol{\theta}, \mathbf{x}_{-T:-1}\}^{[n]}$  from  $p(\boldsymbol{\theta}, \mathbf{x}_{-T:-1} \mid \mathbb{D})$  using a PMCMC method
3:   for  $t = -1, \dots, H$  do
4:     Sample  $\mathbf{v}_t^{[n]}$  from  $\mathcal{V}_{\boldsymbol{\theta}^{[n]}}$ 
5:     Sample  $\mathbf{w}_t^{[n]}$  from  $\mathcal{W}_{\boldsymbol{\theta}^{[n]}}$ 
6:   end for
7:    $\mathbf{x}_0^{[n]} \leftarrow \mathbf{f}_{\boldsymbol{\theta}^{[n]}}(\mathbf{x}_{-1}^{[n]}, \mathbf{u}_{-1}) + \mathbf{v}_{-1}^{[n]}$ 
8: end for

```

---

The samples  $\{\boldsymbol{\theta}, \mathbf{x}_{-T:-1}\}^{[1:N]}$  can be used to generate scenarios  $\boldsymbol{\delta}^{[1:N]}$ , which are samples from the distribution  $p(\boldsymbol{\theta}, \mathbf{x}_0, \mathbf{v}_{0:H}, \mathbf{w}_{0:H} \mid \mathbb{D})$  and represent possible future system behavior depending on  $\mathbf{u}_{0:H}$ . The generation of these scenarios can be seen in Algorithm 1.  $\boldsymbol{\theta}^{[n]}$  is obtained via PMCMC and through it we also know the system dynamics and noise distributions which can be used to draw samples of both the processing noise  $\mathbf{v}_{0:H}$  and measurement noise  $\mathbf{w}_{0:H}$ . Those can then be combined with the  $\mathbf{x}_{-T:-1}$ , or more precisely  $\mathbf{x}_{-1}$  to find the initial state  $\mathbf{x}_0$  to complete the scenario  $\boldsymbol{\delta} = \{\boldsymbol{\theta}, \mathbf{x}_0, \mathbf{v}_{0:H}, \mathbf{w}_{0:H}\}$ . How these scenarios can be used to find an optimal input  $\mathbf{u}_{0:H}$  is described in the next section.

## 2.2 Chance-Constraint Optimization with Kernel Approximation

In the previous section, a method that enables us to generate a finite number of scenarios  $\boldsymbol{\delta}^{[1:N]}$  was presented. These scenarios can be used to formulate an OCP to find an optimal  $\mathbf{u}$  or a control law  $\boldsymbol{\pi}$ . In this section, a method to use maximum mean discrepancy (MMD) ambiguity sets and kernel approximation to reformulate the OCP is proposed.

### 2.2.1 MMD ambiguity sets

As the underlying data distribution  $P$  in the constraints 1.3 is unknown, we first expand the them to their distributionally robust counterpart in order to allow for the use of scenarios as an approximation of the distribution. For this, we consider  $P$  as the worst case distribution within a set  $\mathcal{P}$  of plausible distributions, the so-called ambiguity set. This gives us the new constraints

$$\inf_{\tilde{P} \in \mathcal{P}} \tilde{P}[h(\mathbf{u}_{0:H}, \mathbf{x}_{0:H}, \mathbf{y}_{0:H}) \leq 0] \geq 1 - \alpha. \quad (2.1)$$

To construct the set  $\mathcal{P}$ , a similarity measure is needed to provide a concrete comparison between various distributions  $\tilde{P}$ . Maximum mean discrepancy (MMD) [GBR<sup>+</sup>12] is able to do that by using the norm of the difference between the kernel mean embeddings (KME)  $\|\mu_Q - \mu_{Q'}\|_{\mathcal{H}}^2$  of two distributions  $Q$  and  $Q'$  as a metric between two distributions. The KME are given as  $\mu_Q = \int k(x, \cdot) dx$  with  $k(x, \cdot) \in \mathcal{H}$  being the feature map of the kernel function  $k$ . The metric can then be rewritten as

$$\text{MMD}(Q, Q') = \mathbb{E}_{x, x' \sim Q}[k(x, x')] + \mathbb{E}_{y, y' \sim Q'}[k(y, y')] - 2\mathbb{E}_{x \sim Q, y \sim Q'}[k(x, y)] \quad (2.2)$$

The MMD-based ambiguity set  $\mathcal{P}$  is then constructed as the set of distributions  $\tilde{P}$  in an  $\varepsilon$  radius centered around the empirical distribution  $\hat{P}_N$  which is given through the scenarios  $\boldsymbol{\delta}^{[1:N]}$ . This gives us the set

$$\mathcal{P} = \{P : \text{MMD}(P, P_N) \leq \varepsilon\}. \quad (2.3)$$

The radius  $\varepsilon$  is chosen through constructing a bootstrap MMD ambiguity set as described in [NKSZ22] and is outlined in Algorithm 2. This procedure requires a number of bootstrap samples  $B$  to be chosen, as well as confidence level  $\beta$ . It then utilizes kernels  $k(\boldsymbol{\delta}^{[i]}, \boldsymbol{\delta}^{[j]}) \in \mathbb{R}$  to define the (biased) MMD estimator as

$$\widehat{\text{MMD}}(\tilde{P}, P_N) = \sum_{i,j=1}^N k(\boldsymbol{\delta}^{[i]}, \boldsymbol{\delta}^{[j]}) + k(\tilde{\boldsymbol{\delta}}^{[i]}, \tilde{\boldsymbol{\delta}}^{[j]}) - 2k(\boldsymbol{\delta}^{[i]}, \tilde{\boldsymbol{\delta}}^{[j]}) \quad (2.4)$$

with  $\tilde{\boldsymbol{\delta}}^{[n]}$ ,  $n = 1, \dots, N$ , denoting a bootstrap sample of  $P_N$  where samples are drawn with replacement from  $\boldsymbol{\delta}^{[1:N]}$ . Finally,  $\widehat{\text{MMD}}(\tilde{P}, P_N)$  is calculated for all  $B$  bootstrap samples, the results are saved in list and  $\varepsilon$  is chosen as the  $\text{ceil}(B\beta)$ -th element of the sorted list.

### 2.2.2 Constraint Reformulation

With a given MMD ambiguity set  $\mathcal{P}$ , the feasible set of each constraint 1.4 is given as

$$Z_i := \left\{ \mathbf{u}_{0:H} \in \mathcal{U}^{H+1} : \inf_{P \in \mathcal{P}} P \left[ \tilde{h}_i(\mathbf{u}_{0:H}, \boldsymbol{\delta}) \leq 0 \right] \geq 1 - \alpha \right\}. \quad (2.5)$$

with  $\tilde{h}_i(\mathbf{u}_{0:H}, \boldsymbol{\delta}) = h_i(\mathbf{u}_{0:H}, \mathbf{x}_{0:H}, \mathbf{y}_{0:H})$

We can now use the ambiguity set  $\mathcal{P}$  defined in Sec. 2.2.1 with the radius  $\varepsilon$ , as well as the kernel matrix  $\mathbf{K}$  to reformulate the feasible set. By following the steps described in [NKSZ22], we can obtain the new reformulated feasible set as

**Algorithm 2** Bootstrap MMD ambiguity set**Input:** Scenarios  $\delta^{[1:N]}$ , Number of bootstrap samples  $B$ , Confidence level  $\beta$ **Output:** Gram matrix  $\mathbf{K}$ , Radius of MMD ambiguity set  $\varepsilon$ 

---

```

1:  $\mathbf{K} \leftarrow \text{kernel}(\delta, \delta)$ 
2: for  $m = 1, \dots, B$  do
3:    $I \leftarrow N$  numbers from  $\{1, \dots, N\}$  with replacement
4:    $K_x \leftarrow \sum_{i,j=1}^N K_{ij}$ ;
5:    $K_y \leftarrow \sum_{i,j \in I} K_{ij}$ ;
6:    $K_{xy} \leftarrow \sum_{j \in I} \sum_{i=1}^N K_{ij}$ ;
7:    $\text{MMD}[m] \leftarrow \frac{1}{N^2} (K_x + K_y - 2K_{xy})$ ;
8: end for
9:  $\text{MMD} \leftarrow \text{sort}(\text{MMD})$ 
10:  $\varepsilon \leftarrow \text{MMD}[\text{ceil}(B\beta)]$ 

```

---

$$Z_i := \left\{ \mathbf{u}_{0:H} \in \mathcal{U}^{H+1} : \begin{aligned} &g_0 + \frac{1}{N} \sum_{n=1}^N (\mathbf{K}\boldsymbol{\gamma})_n + \varepsilon \sqrt{\boldsymbol{\gamma}^\top \mathbf{K} \boldsymbol{\gamma}} \leq t\alpha \\ &[\tilde{h}_i(\mathbf{u}_{0:H}, \boldsymbol{\delta}^{[n]}) + t]_+ \leq g_0 + (\mathbf{K}\boldsymbol{\gamma})_n, \quad n = 0, \dots, N \\ &g_0 \in \mathbb{R}, \boldsymbol{\gamma} \in \mathbb{R}^N, t \in \mathbb{R} \end{aligned} \right\} \quad \begin{aligned} (2.6a) \\ (2.6b) \\ (2.6c) \end{aligned}$$

where  $[\cdot]_+ = \max(0, \cdot)$  denotes the max operator. The new set also contains new variables that have to be taken into account when solving the OCP. The variables  $g_0$ ,  $\gamma$  and  $t$  are the degrees of freedom that  $u$  has at each constraint. The former are parameters of the RKHS function that was used to transform the problem into a kernel machine learning problem while  $t$  has been introduced as a way to relax the risk factor  $\alpha$ .

This approximation can then be repeated for all other constraints  $\mathbf{h}(\cdot)$  to obtain the feasible sets  $Z_i, i = 1, \dots, n_c$ . We can then use those constraints to formulate the OCP as

$$\min_{\mathbf{u}_{0:H}, \{\gamma, g_0, t'\}^{[1:n_c]}} J_H(\mathbf{u}_{0:H}) \quad (2.7a)$$

$$\text{s.t. } \forall n = 1, \dots, N, \forall t = 0, 1, \dots, H, \forall i = 1, \dots, n_c \quad (2.7b)$$

$$\mathbf{x}_{t+1}^{[n]} = \mathbf{f}_{\theta^{[n]}}(\mathbf{x}_t^{[n]}, \mathbf{u}_t) + \mathbf{v}_t^{[n]} \quad (2.7c)$$

$$\mathbf{y}_t = \mathbf{g}_{\theta^{[n]}}(\mathbf{x}_t^{[n]}, \mathbf{u}_t) + \mathbf{w}_t^{[n]} \quad (2.7d)$$

$$\mathbf{u}_{0:H} \in Z_i(\gamma^{[i]}, g_0^{[i]}, t'^{[i]}) \quad (2.7e)$$

As described in Sec. ??, we are minimizing a cost function  $J_H$ . The system dynamics are included through the constraints 2.7c and 2.7d and must be fulfilled for all scenarios as well. Lastly, the input  $u_{0:H}$  is restricted to the feasible sets  $Z_i$ , i.e.  $u_{0:H}$  must be an element of all  $Z_i, i = 1, \dots, n_c$ .

The optimization problem 2.7 is deterministic and, with the uncertainties removed, can be solved with well known methods.

# Chapter 3

## Evaluation

In this section, the proposed optimal control approach is implemented and its effectiveness tested and compared to the previous approach. The simulation setup is described in Sec. ?? and ??. The results of the OCP are shown in Sec. 3.2. Afterwards, we analyse the results and performance in more detail in Sec. 3.3 and Sec. 3.4 by looking at the robustness of the solution and the computation times of the optimization process and compare it to the commonly used scenario approach.

### 3.1 Simulation Setup

We consider a system with the state transition function

$$\mathbf{f}(\mathbf{x}, u) = \begin{bmatrix} 0.8x_1 - 0.5x_2 \\ 0.4x_1 + 0.5x_2 + u \end{bmatrix} \quad (3.1)$$

and the process noise distribution

$$\mathbf{v}_t \sim \mathcal{N}\left(\mathbf{0}, \begin{bmatrix} 0.03 & -0.004 \\ -0.004 & 0.01 \end{bmatrix}\right). \quad (3.2)$$

Both the state transition function and the process noise distribution are unknown to the user. Meanwhile, the observation function  $g(\mathbf{x}, u) = x_1$  and measurement noise  $w_t \sim \mathcal{N}(0, 0.1)$  are known.

For the scenario generation, we consider a set containing  $T = 2000$  input and output measurements of the true system for our dataset  $\mathbb{D}$ . These measurements are obtained with a random input trajectory  $u \sim \mathcal{N}(0, 3)$  while starting from a random initial state  $\mathbf{x}_T \sim \mathcal{N}([2, 2]^T, \mathbf{I}_2)$ . To infer the state model parameters, the approach from [ADH17] is used. It is assumed that  $\mathbf{f}(\cdot)$  is a linear combination of  $n_a$  basis functions  $\varphi(\mathbf{x}_t, u_t)$  and the process noise is normally distributed. As such, the state transition can be rewritten as

$$\mathbf{x}_{t+1} = \mathbf{A}\varphi(\mathbf{x}_t, u_t) + \mathbf{v}_t \quad (3.3)$$

with the basis functions  $\varphi(\mathbf{x}, u) = [x_1, x_2, u]^T$ , the process noise  $\mathbf{v}_t \sim \mathcal{N}(\mathbf{0}, \mathbf{Q})$  and the unknown parameters  $\boldsymbol{\theta}$  consisting of  $\mathbf{A}$  and  $\mathbf{Q}$ . An inverse Wishart prior with  $l$  degrees of freedom and positive definite scale matrix  $\Lambda$  is assumed for the matrix  $\mathbf{Q}$ . For the matrix  $\mathbf{A}$  matrix normal prior with mean matrix  $\mathbf{M} = \mathbf{0}$ , right covariance  $\mathbf{U} = \mathbf{Q}$  and left covariance matrix  $\mathbf{V} \in \mathbb{R}^{n_a \times n_a}$ . For the estimation of the posterior distribution with the PG sampler, we scale the basisvector with the weights  $[0.1, 0.1, 1]^T$  and for the prior the weights are chosen as  $\mathbf{V} = 10\mathbf{I}_5$ .

We use gaussian kernels  $k(x, y) = \exp\left(-\frac{1}{2\sigma^2}\|x - y\|_2^2\right)$  with the bandwidth  $\sigma$  set individually for all random parameters  $\{\mathbf{x}_0^{[k]}, \mathbf{v}_{0:H}^{[k]}, \mathbf{w}_{0:H}^{[k]}, \mathbf{A}^{[k]}\}$  via the median heuristic [GJK18] and scaled with the factors  $[1.5, 5, 5, 1]^T$ . As such, the elements of the Gram matrix  $\mathbf{K} \in \mathbb{R}^{N \times N}$  are defined as

$$K_{ij} = k_A(\mathbf{A}^{[i]}, \mathbf{A}^{[j]})k_{\mathcal{X}}(\mathbf{x}_0^{[i]}, \mathbf{x}_0^{[j]})k_{\mathcal{V}^H}(\mathbf{v}_{0:H}^{[i]}, \mathbf{v}_{0:H}^{[j]})k_{\mathcal{W}^H}(\mathbf{w}_{0:H}^{[i]}, \mathbf{w}_{0:H}^{[j]}). \quad (3.4)$$

## 3.2 Optimal Control with Constrained Output

In the following, we show how well the proposed optimal control approach works when applied to a OCP with constrained output by putting it side by side with the solution of the same problem where we have used the Scenario approach which implements the chance-constraints by ensuring that the constraints are satisfied for every scenario  $n \in \mathbb{N}_{\leq N}$ .

For this simulation, we are scenarios that have been generated using the PG sampler. To this end, 9170 samples were created and the first  $N_p = 1000$  were discarded as training samples and the remaining samples were once again thinned with  $n_d = 30$ . The remaining  $N = 200$  samples are then used as scenarios for the OCPs.

For the cost function, we consider a simple quadratic cost  $J_H = \sum_{t=0}^H u_t^2$  over the horizon  $H = 40$ . For constraints, we consider the input-constraint  $|u| \leq 10$  as well as the temporarily active output-constraints  $y_{10:20} \leq -10$  and  $10 \leq y_{30:40}$ . The risk level  $\alpha$  is fixed at 0.1 for this experiment and  $\epsilon$  is chosen through Algorithm 2.

The OCP can then be formulated as described in ???. Since the problem has been chosen as convex in this example, a solution for both the scenario and kernel approach can be found easily by using a convex solver. The results of an exemplary run is shown in Fig. 3.1.

The figure includes the two plots for the scenario and kernel approach and shows the output  $y$  of their respective OCPs. The graphs shows the spread of the  $N = 200$  trajectories that are generated when the input  $\mathbf{u}_{0:H}$  is applied to the scenarios that were used to find the optimal input. On top that, it also shows of the mean of these trajectories and true output. Where the two graphs differ however is to what extend the solutions fulfill the constraints. By its definition, the scenario approach requires all scenarios to fulfill the constraints which can be seen in the solution. While the gray area touches the min and max constraints in several places, it never violates the constraints. The kernel approach on the other hand has a risk factor  $\alpha$  built in

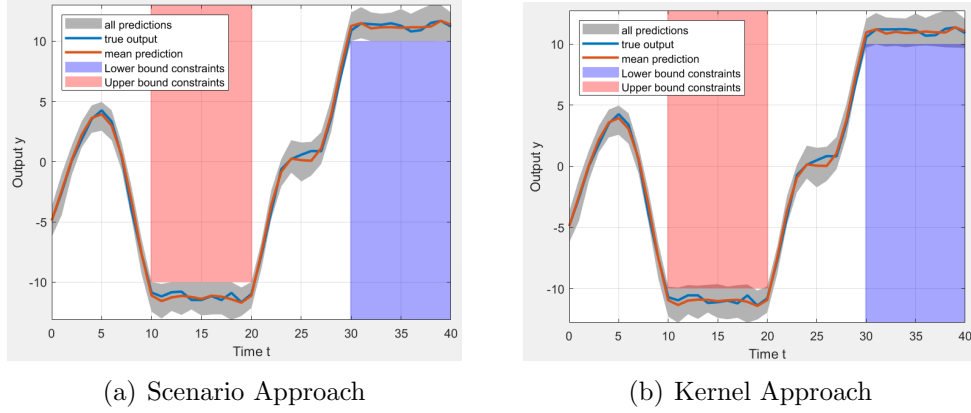

Figure 3.1: Example of the optimal control with known basis functions for scenario approach (left) and kernel approach (right). The red and blue area show the output constraints. The gray area encompasses the 200 scenarios that were used in the optimization with the orange line being the average. The blue line is one realization of the true output.

which allows for a number of scenarios to violate the constraints as long as a sufficient number satisfies them. This can be seen in the constraint still being met by the majority of the scenarios and only the trajectory of a small number of scenarios actively overlapping with the marked area. As a result, a solution with a lower cost was found in exchange for an increased risk of the true output violating one or more of the constraints.

### 3.3 Robustness

The biggest advantage that this kernel approximation proves compared to the scenario approach is the adjustable risk factor. As described in Sec. 2.2, this method includes a parameter  $\alpha \in [0, 1]$  which can be chosen depending on how successful the final solution is supposed to be when it comes to satisfying the constraints in future scenarios.

In this section, this parameter is tested by running the same problem setup as was used in Sec. 3.2 for different values of  $\alpha$  as well as an increasing number of samples  $N$  and testing how well the solution holds up for future scenarios.

Similar to Sec. 3.2, a number of scenarios are generated with Algorithm 1. From this set scenarios, a small subset is then taken and used to formulate several OCPs as was already described in Sec. 3.2. The OCPs are then solved and the resulting optimal input  $\mathbf{u}_{0:H}$  is then used on  $N = 2000$  more independent scenarios from the same system to test how well this solution holds up. For each of the 2000 scenarios, the output is calculated and compared to the constraints that were used in the OCP to check whether or not they are fulfilled. This process is then repeated for various

numbers of scenarios. It is done for 1, 5, 10 and 25 samples and then increased with a step size of 25 until a  $N = 250$  samples are used in the optimization.

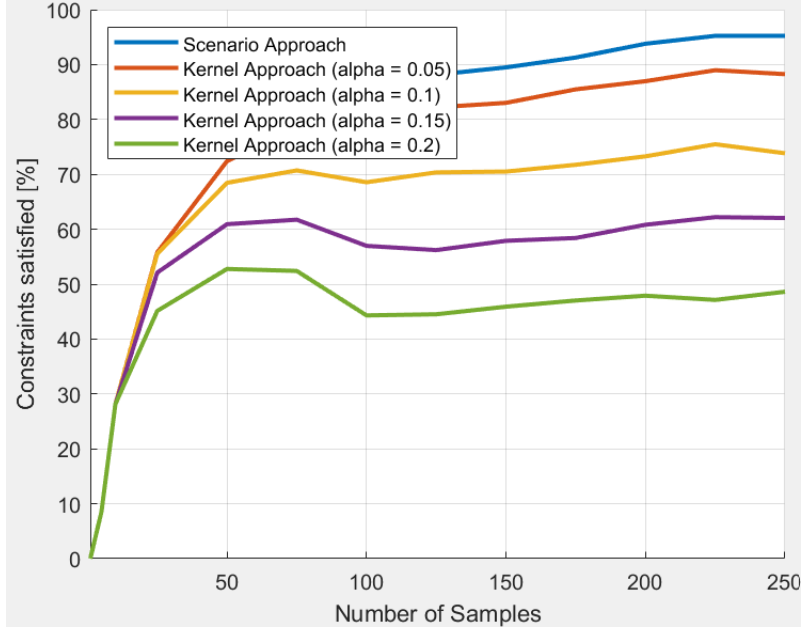

Figure 3.2: Percentage of scenarios where  $u_{0:H}$  is a viable solution. The blue line shows the result of the scenario approach while the other lines are for the Kernel approach with various values of  $\alpha$

In Fig. 3.2 the results of this simulation are shown. The percentage of scenarios that fulfill the constraints is plotted over the number of samples used in the initial optimization which range from  $N = 1$  to 250. The various  $\alpha$  values are shown as separate lines. Initially, all five plots show very similar results. This can be explained by the fact that at such a low number of scenarios cannot accurately represent the distribution. As the number of scenarios is increased, the approximation of the distribution becomes better leading to a higher percentage of scenarios where the constraints are satisfied.

After around 10 scenarios, the plots start diverging for the first time. While the scenario approach and the plots with smaller  $\alpha$  values are very similar, the lines that represent larger  $\alpha$  values are starting to display worse percentage of cases that satisfy the constraints. This trend continues as the number of scenarios used in the optimization keeps increasing. While the scenario approach keeps increasing, the kernel approach seems to converge to a significantly lower level of robustness based on the selection of the parameter  $\alpha$ . This shows that through  $\alpha$  we are able to control how distributionally robust the solution is.

### 3.4 Computation Time

While the previous sections focused on comparing the results of the Scenario approach to the kernel approach, the runtime of both methods is another important factor that needs to be considered when choosing which algorithm is best suited for a specific problem. As such, Fig. 3.3 shows the runtime of both scenario approach and kernel approach over the number of scenarios that are used to formulate the OCPs. The parameters and constraints are chosen the same as in Sec. 3.2. When looking at the figure, it quickly becomes apparent that while both curves start around the same level, the kernel approach runtime increases significantly faster and with more of a curvature than the scenario approach. By the end of the plot, the kernel approach already takes about 5 times as long as the scenario approach. This shows that at least when it comes to finding a solution quickly, the Scenario approach is still the better choice.

Figure 3.3: Runtime over number of scenarios  $N$  for scenario and kernel approach

## Chapter 4

# Discussion

Discuss and explain your results. Show how they support your thesis (or, if they do not, give a convincing explanation). It is important to separate objective facts clearly from their discussion (which is bound to contain subjective opinion). If the reader does not understand your results, reconsider if you have managed to extract the core information and explain it in a straightforward way.

## Chapter 5

## Conclusion

# List of Figures

- 3.1 Example of the optimal control with known basis functions for scenario approach (left) and kernel approach (right). The red and blue area show the output constraints. The gray area encompasses the 200 scenarios that were used in the optimization with the orange line being the average. The blue line is one realization of the true output. 17
- 3.2 Percentage of scenarios where  $u_{0:H}$  is a viable solution. The blue line shows the result of the scenario approach while the other lines are for the Kernel approach with various values of  $\alpha$  . . . . . 18
- 3.3 Runtime over number of scenarios  $N$  for scenario and kernel approach 19
